and Other Early Collection Plants.

Orig Pub: Vcelarstvi, 1958, 11, No 4, 50-51.

Abstract: After several years of observation, the authors drew the conclusion that under the conditions of Czechoslovakia the employment of two-colony, two-body beehives proves more efficient than when the usual one-queen beehives are used. In a two-colony beehive, colony A is arranged at the top of the beehive structure, colony B at the bottom. A sheet of foil is placed between the chambers in order to separate the odors of each colony. Usually, colony

TITLE: Application of the radiospectrometer EPR-2 in the study of radicals formed during the oxidation of antioxidants

PERIODICAL: Chemický průmysl, no. 2, 1963, 74 - 77

TEXT: Many antioxidants form stable free radicals on oxidation and it is suggested that the effectiveness of such compounds may depend on the stability and structure of the resulting free radicals. Electron magnetic resonance spectra are reported for radicals formed by oxidation with lead dioxide of the following substituted phenols in a cyclohexane or benzene medium: 2,6-di-tert.butyl-4-methylphenol, (I) thio-bis-(2-methyl-5-tert.-butylphenol), (II), phenyl-bis-(3-tert.butyl-6-methyl phenyloxy)-methane, (III), and ethylene-bis-(2-methyl-5-tert.butylphenol), (IV). The spectra were obtained at room temperature using a microwave frequency of 9750 Mc/s. The phenol and solvent were contained in a 5-mm diameter tube, the solvent being frozen by means of liquid nitrogen to which the oxidizing agent was added. The tube was
Card 1/3

Application of

evacuated and inserted into the resonator when, the solvent having melted, the formation of the radicals began. Results appeared in the conventional way as derivatives of the absorption curves. The oxidation of (I) proceeds in two stages and the spectra and identities of the primary and secondary radicals are shown. The quartet splitting, seen in the spectra, is associated with the three hydrogens of the methyl group in the p-position. The hyperfine triplet splitting of each line must be associated with the interaction of the unpaired electron with the meta ring hydrogen atoms. A study of the second phase of oxidation revealed the disappearance of the basic quartet and replacement by a narrow triplet. Results suggest that the p-methyl group is being oxidized to a COH or COOH-group. The oxidation of (II) showed abstraction of the phenolic hydrogen atom and interaction of the unpaired electron with the hydrogens of the methyl groups and of the benzene ring. The spectrum did not show hyperfine structure. Oxidation of (III) gave spectra with symmetrical singlets and hyperfine structure. The spectra of the free radicals from (IV) gave a symmetrical singlet. There are 4 figures.

TITLE: Stabilized source for constant current coulometry

SOURCE: Chemické listy, v. 59, no. 5, 1965, 604-607, and insert facing p. 608

TOPIC TAGS: titrimetry, chemical laboratory apparatus, microchemical analysis 27

Abstract: Coulometric titration at constant current are used in analysis conducted on large numbers of samples. There are however very few sources for the supply of suitable apparatus. The authors describe an apparatus of their own design; it has a range of 0.2 to 40 mA and it is suitable for analysis where a limited amount of the analyzed substance is available, or for microanalysis. It is suitable for concentrations of 0.05 to 3 microequiv/ml, in iodometric determination of small amounts of H_2S (2 to 50 micrograms), and in titanometric determination of iron (0.002%) in Ti salts. Orig. art. has 3 figures and 2 graphs.

ABSTRACT:

Hedgehogs are highly susceptible to very small subcutaneous doses of tick-borne encephalitis virus. Subcutaneous doses of 0.1 LD₅₀ produce severe and prolonged viremia. The disease has two peaks, one on the 4th-6th day after infection, and the second on the 12th-15th day. Complement-fixing antibodies appeared in the blood on the tenth day after infection, reached their highest titer on the thirtieth day and were nearly absent by the

AUTHOR: Romanova, A. V.; Kuchak, G. M.

TITLE: X-ray investigation of molten intermetallic compounds of the indium-bismuth system /Sixth Conference on the Physics of Liquid State of Matter held in Kiev in 1963/

SOURCE: Ukrayins'ky* y fizy*chny* y zhurnal, v. 9, no. 4, 1964, 428-440

TOPIC TAGS: indium bismuth system, indium bismuth alloy structure, molten alloy structure, molten compound structure, molten In sub 2 Bi, molten InBi, InBi structure, In sub 2 Bi structure

ABSTRACT: The structure of molten InBi and In₂Bi intermetallic compounds (melting temperatures are 110 and 91C, respectively) vacuum-melted from 99.99% pure In and Bi has been investigated at 120, 220, and 320C by means of x-ray diffraction method. It was found that at temperatures 10C higher than the melting temperature no correlation exists in InBi between the atom distribution in the liquid and in the crystal lattice. The structure of InBi alloy is mainly determined by a "quasi-eutectic" atom distribution in micro-regions whose structure is similar to that of the molten
Card 1/3

ACCESSION NR: AP4040377

predominantly pure components. The structure remains unchanged up to 320C, above which the In microregions begin to enrich with Bi atoms in an amount exceeding their solubility in the In lattice, i.e., 12.5 at%. It appears possible that at 120C about 20% of the atoms in the liquid InBi form groups with the atom distribution corresponding to that in the crystal lattice. A similar pattern was observed in liquid In₂Bi at 120C except that a greater amount of atoms (about 30—40%), participate in the formation of groups with atom distribution similar to that in the crystal lattice. At 220C, the regions with the structure resembling that of the crystalline lattice and the "quasi-eutectic" structure break up, while the number of regions with a close-packed structure (coordination number = 11) increases. The atom interaction in liquid InBi at 120—320C is determined mainly by groups of atoms of one kind, whereas in the crystal lattice atoms of both kinds are at the least interatomic distances (3.09, 3.54, 4.06Å). In liquid In₂Bi at 120C the atom interaction is determined partly by preserving the bond of the same nature as in the crystal and partly by grouping atoms of the same kind. In an ordered crystal lattice there are atoms of different kinds at the least distances. Orig. art. has: 9 figures, 1 table, and 3 formulas.

TITLE: Local heating at the contact points of solid particles in a granular layer

SOURCE: AN SSSR. Doklady, v. 167, no. 6, 1966, 1335-1337

TOPIC TAGS: grain structure, granule formation, solid mechanics, catalytic heat transfer

ABSTRACT: The purpose of this investigation was to calculate the heating in the vicinity of the contact points of solid particles. It is proposed that this process occurs in the gas phase, namely that in this case the danger of the occurrence of overheating is the highest. Since the molecular heat conductivity of gases is incomparably less than that of a solid particle, the authors consider that heat transfer from the point of contact is accomplished only through the solid phase. It is proposed that the reaction proceeds on the outside surface of the particles. The limiting diffusion flow on the surface of the catalyst in the stagnant zone is determined and appropriate formulas are given. By knowing the flow of the substance on the surface of the catalyst the authors solved the problem of the distribution of temperature in a

Card 1/2

UDC: 66.097.13

L 38930-66

ACC NR: AP6013902

grain close to the point of contact, disregarding the curvature of the particle and considering it flat since the dimension of the stagnant zone is appreciably smaller than the radius of the particle. It was found that heating increases with a rise of pressure as a consequence of the increase of the gas density, and that in diluted gas mixtures or when the reaction occurs on monolithic metal catalysts, heating is negligible at the point of contact. The paper was presented by Academician A. N. Frumkin 28 July 65. The authors thank V. G. Levich for his interest in the work and his valuable advice. Orig. art. has: 1 figure and 18 formulas.

The theory of electroluminescence in ZnS crystals. Karel Kuchal (Karlova Univ., Prague). *Czechoslov. J. Phys.* 9, 670-68 (1960) (in German).—The author assumes that electroluminescence is due to recombination of electrons from the surface with ionized activator centers in the vol. of the crystal (Zahn, *Thesis*, Univ. Amsterdam 1956). A theoretical model is developed which is compared with the exptl. results of other authors with respect to voltage, frequency, and temp. dependence. A. Kremheller
